

1. **Identify the main components of the system.** The system consists of three main components: the user interface, the data storage, and the processing logic.

2. **Define the data structure.** The data is stored in a database with the following structure: a table named 'users' with columns for 'id', 'name', 'email', and 'password'.

3. **Implement the logic.** The logic for the system is implemented in a series of steps: first, the user interface is designed; then, the data storage is set up; and finally, the processing logic is implemented.
